## ID CLAIMS

Following recommendations of the 1974 work done on the ID, a detailed geochemical contour line along the anomalous creek was carried out and a trench was dug and sampled. Results of this geochemical traverse appear on Figure 2.

Both the trenching and the geochemical results were disappointing. From the geochemical results, it can be surmised that the two gossanous mineralized areas are not joined under the talus. It is probable that there are only two or three very localized occurrences along the same bed. Controls for these localizations are not known because of talus cover.

In summary, there is little evidence of sufficient mineralization that would justify further work being done on the ID group at this time.
